Jaime Arguello INLS 509: Information Retrieval

jarguell@email.unc.edu

September 18, 2017

How should this document be represented?

Elements of a Document Representation

- Document attributes (metadata)
 - source, publication date, language, length, etc.
- Controlled vocabulary index terms
- Free-text index terms
 - terms selected from the document text itself
 - may also include text from <u>outside</u> the document (e.g., anchor text)
 - lots of room for creativity!

Elements of a Document Representation

controlledvocabulary index terms

Elements of a Document Representation

Text Processing

gerard salton 8 march 1978 in nuremberg 28 august 1995 also know as gerry salton was professor of computer science at cornell university salton was perhaps the leading computer scientist working in the field of information retrieval during his time his group at cornell developed the smart information retrieval system which he initiated when he was at harvard

- Our goal is to describe content using content
- After mark-up removal, down-casing, and tokenization, what we have is a sequence of terms
- What are the most descriptive words?

Salton was editor-in-chief of the Communications of the ACM and the Journal of the ACM, and chaired SIGIR. He was an associate editor of the ACM Transactions on Information Systems. He was an ACM Fellow (elected 1996), received an Award of Meltr from the American Society for Information Science (1998), and was the first recipient of the SIGIR Award for outstanding contributions to study of information retrieval (1983) — now called the Gerard Salton Award.

Stopwords

- A stopword is a term that is discarded from the document representation
- Typically the <u>same</u> set of stopwords is used in processing all documents in the collection
- Stopwords are typically function words: determiners (a, the), prepositions (on, above), conjunctions (and, but)
- May also be corpus-specific: "plot" in the IMDB corpus
- Assumption: stopwords are unimportant because they are frequent in <u>every</u> document

Lemur Stopword List

first 60 (sorted alphabetically)

a	all	amongst	anywhere	become	besides
about	almost	an	apart	becomes	between
above	alone	and	are	becoming	beyond
according	along	another	around	been	both
across	already	any	as	before	but
after	also	anybody	at	beforehand	by
afterwards	although	anyhow	av	behind	can
again	always	anyone	be	being	can
against	am	anything	became	below	cannot
albeit	among	anyway	because	beside	canst

associate editor of the ACM Transactions on Information Systems. He was an ACM Fellow (elected 1995), received an Award of Merit from the American Society for Information Science (1999), and was the first recipient of the SIGIR Award for outstanding contributions to study of information retrieval (1993) – now called the Gerard Salton Award.

Term-Frequencies after stopword removal

5	vector	8	15	frequency	4
6	S	7	16	science	4
7	term	7	17	cornell	4
8	automatic	7	18	award	3
9	gerard	6	19	0	3
10	space	6	20	8	3

Creating a Stopword List

- Sort vocabulary based on frequency in the corpus
- Examine the most frequent words
- Examine a query-log to see which frequent terms may be important
- 38% of unique AOL queries contain at least one stopword (may or may not be important - more later)
- 0.025% of unique AOL queries are nothing but stopwords
 - longest: i want something else to get me through this (third eye blind lyrics)

Trends in Stopword Removal

- The earliest systems used stopword lists of 200-300 terms
- To improve efficiency and effectiveness
- Very frequent terms were problematic for early retrieval models (e.g, OR operations in ranked boolean)
- Web search engines generally do not remove stopwords
- The latest trend is to index stopwords and (possibly) ignore them at query-time if they seem unimportant
- Newer retrieval models are better at handling very frequent terms (later lecture)

Morphology

• the study and description of word formation (as inflection, derivation, and compounding) in language

Merriam-Webster Dictionary

Morphology

- Inflectional morphology: changes to a word that encode its grammatical usage (e.g., tense, number, person)
 - say vs. said, cat vs. cats, see vs. sees
- Derivational morphology: changes to a word to make a new word with related meaning
 - organize, organization, organizational
- Compounding: combining words to form new ones
 - shipwreck, outbound, beefsteak
 - more common in other languages (e.g., german)
 - lebensversicherungsgesellschaftangestellter

Morphological Analysis in information retrieval

- Basic question: words occur in different forms. Do we want to treat different forms as different index terms?
- Conflation: treating different (inflectional and derivational) variants <u>as the same index term</u>

in information retrieval

 Conflation: treating different (inflectional and derivational) variants <u>as the same index term</u>

image	images	imaging	imag* (root form)
df=6	df=4	df=3	df=6
1,4	1,4	1,4	1, 12
10, 1	10, 5	10, 5	10, 11
15, 2	16, 1	16, 1	15, 2
16, 1	68, I		16, 3
33, 5			33, 5
68 , 7			68 , 8

docid, term frequency

Morphological Analysis in information retrieval

- What are we trying to achieve by conflating morphological variants?
- Goal: help the system ignore <u>unimportant</u> variations of language usage

in information retrieval

 The query "computer repairs" will match all combinations of:

computers
computing
computation
computational

and

repairs
repaired
repairing
repairable

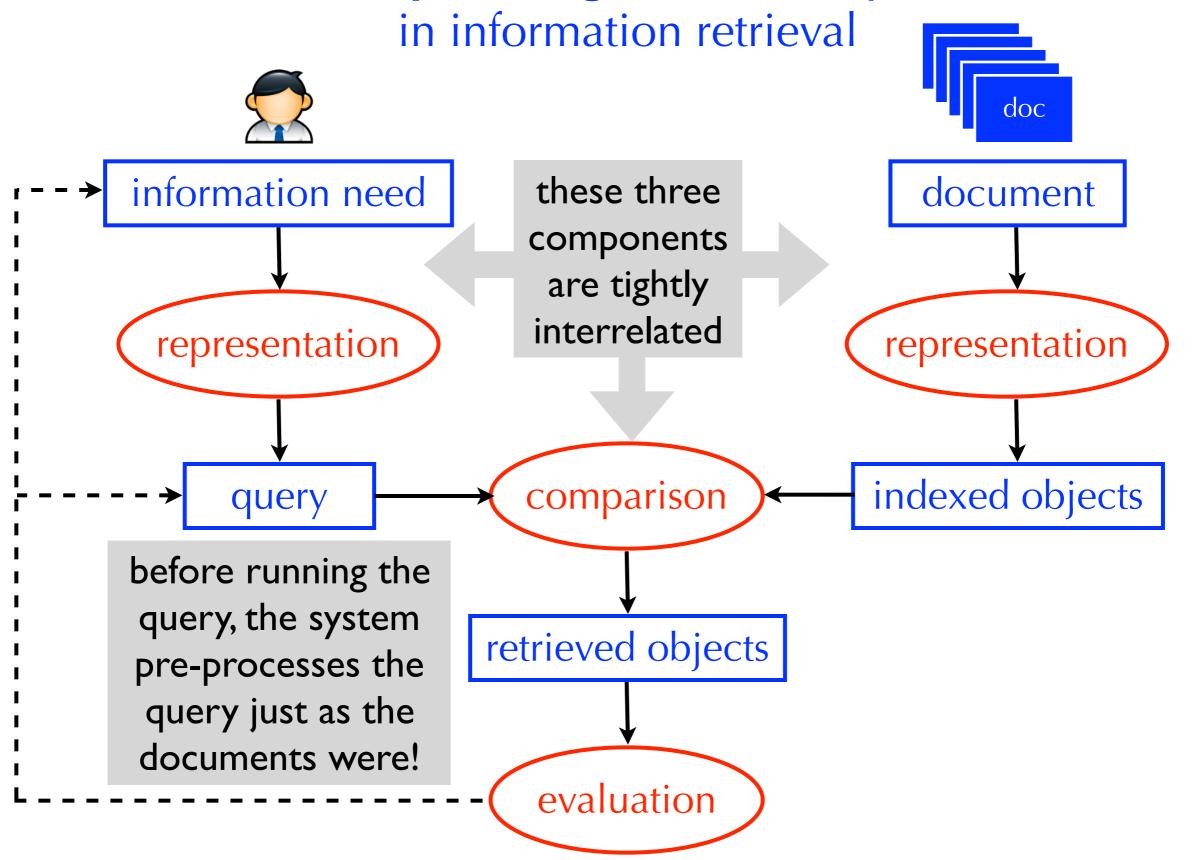

in information retrieval

- In English, conflating morphological variants is usually done using a stemmer
- Stemming: automatic suffix-stripping
- English word variations occur at the end of a word
- root/stem + suffix
 - repair + s/ed/ing/able
- A stemmer conflates different variations by reducing them to a common root/stem

in information retrieval

- In some cases, whatever is left after suffix-stripping is not even a word (e.g., comput)
- Is this a problem?

```
computers repairs
computing repaired
computation repairing
computational repairable
::
```

the porter stemmer (porter '80)

- A long list of rules that are applied in sequence
 - apply the rule that removes the longest suffix
 - check to see that the stem is likely to be a root (replac+ement vs. c+ement)
- Fast, effective, and, therefore, <u>very</u> popular

Martin Porter's Home Page

No doubt you came here out of idle curiosity from the <u>Porter Stemming Algorithm</u> page. Before you hastily return, you are welcome to look at the following.

This (jerkily) spinning can is the work of <u>Philip Holmes</u> <u>Esquire</u>, ingenious graphic designer and inventor of visual puns. I could never have thought up anything so clever. (Apologies to the Dr Pepper people!)

the porter stemmer (porter '80)

• Example step (1 of 5)

Step 1a:

- Replace sses by ss (e.g., stresses \rightarrow stress).
- Delete s if the preceding word part contains a vowel not immediately before the s (e.g., gaps \rightarrow gap but gas \rightarrow gas).
- Replace *ied* or *ies* by *i* if preceded by more than one letter, otherwise by ie (e.g., ties \rightarrow tie, cries \rightarrow cri).
- If suffix is us or ss do nothing (e.g., stress \rightarrow stress).

Step 1b:

- Replace *eed*, *eedly* by *ee* if it is in the part of the word after the first non-vowel following a vowel (e.g., agreed \rightarrow agree, feed \rightarrow feed).
- Delete *ed*, *edly*, *ing*, *ingly* if the preceding word part contains a vowel, and then if the word ends in *at*, *bl*, or *iz* add *e* (e.g., fished → fish, pirating → pirate), or if the word ends with a double letter that is not *ll*, *ss* or *zz*, remove the last letter (e.g., falling→ fall, dripping → drip), or if the word is short, add *e* (e.g., hoping → hope).
- Whew!

the porter stemmer (porter '80)

 Google seems to be doing stemming. They must think it helps

Big Picture

- Text-processing requires making decisions about what to store in the index
- Two big decisions: stopword-removal and stemming
- My own recommendation (take it, leave it, question it)
 - remove stopwords only if you have to (don't have enough disk-space)
 - off-load the job to query-processing (removing stopwords from the query)
 - stem depending on the importance of recall and the size of the collection

What about homonyms?

(words that are spelled the same, but have different meaning)

Words often have multiple senses

- bank (noun)
 - 1. the rising ground bordering a lake, river, or sea
 - 2. a mound, pile, or ridge above the surrounding level
 - 3. a steep slope (as in "bank of a hill")
 - 4. an establishment for the custody, loan, exchange, and issue of money
 - 5. a supply of something held in reserve
 - 6. the lateral inward tilt of a vehicle (as an airplane) when turning

(Merriam-Webster Dictionary)

 Given a word in a particular context, automatically predict its correct sense from a finite set (bank 1-6)?

"I stopped by the bank to deposit some cash."

An establishment for the custody, loan, and exchange of money

"I stopped by the food bank to donate some food."

A supply of something held in reserve

- An active area of research since the 1950's
- How would you do this?

 Predict the sense whose definition contains terms that co-occur often with those in the surrounding context "I stopped by the bank to deposit some cash."

An establishment for the custody, loan, and exchange of money

, 1
mutual
information
from IMDB
corpus

money	raise	2.686
debt	money	2.578
<u>dollars</u>	money	2.567
money	cash	2.546
buy	money	2.471
money	gambling	2.436
money	pay	2.427
money	bank	2.387
insurance	money	2.117
money	paid	2.018

in information retrieval

- 1. Expand the indexed vocabulary so that each sense of a word is a <u>different</u> index term
- 2. Automatically predict the correct sense for each word in the collection (e.g, bank¹, bank², ..., bank⁶)
 - lots of context (i.e., surrounding text)
- 3. Index the collection as usual
- 4. At query-time, predict the correct word sense in the query (e.g., "drive-through bank4 carrboro")
 - more difficult, not much context
- 5. Retrieve documents as usual

Does it improve (average) retrieval effectiveness?

Not much. Why not?

- Not really a problem for long-queries (other query terms disambiguate the ambiguous ones)
- In theory, can improve performance for short queries
- However, these are precisely the queries for which disambiguation is the most difficult (not much context)

• There is another reason. What is it?
