Predictive Analysis of Text: Concepts, Features, and Instances

Jaime Arguello jarguell@email.unc.edu

August 29, 2017

Predictive Analysis of Text

 Objective: developing and evaluating computer programs that automatically detect a particular concept in natural language text

Predictive Analysis basic ingredients

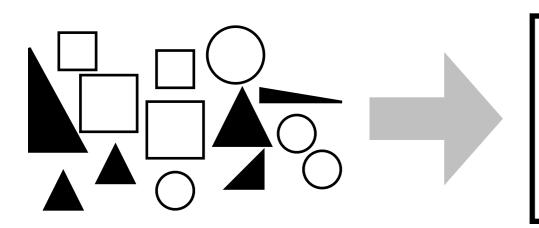

- 1. Training data: a set of positive and negative examples of the concept we want to automatically recognize
- 2. Representation: a set of features that we believe are useful in recognizing the desired concept
- 3. Learning algorithm: a computer program that uses the training data to learn a predictive model of the concept

Predictive Analysis basic ingredients

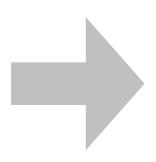

- 4. Model: a function that describes a predictive relationship between feature values and the presence of the concept
- 5. Test data: a set of previously unseen examples used to estimate the model's effectiveness
- 6. Performance metrics: a set of statistics used to measure the predictive effectiveness of the model

predictions

Predictive Analysis questions

- Is a particular concept appropriate for predictive analysis?
- What should the unit of analysis be?
- How should I divide the data into training and test sets?
- What is a good feature representation for a task?
- What type of learning algorithm should I use?
- How should I evaluate my model's performance?

- Learning algorithms can recognize some concepts better than others
- What are some properties of concepts that are easier to recognize?

Option 1: can a human recognize the concept?

- Option 1: can a human recognize the concept?
- Option 2: can two or more humans recognize the concept independently and do they agree?

- Option 1: can a human recognize the concept?
- Option 2: can two or more humans recognize the concept independently and do they agree?
- Option 2 is better.
- In fact, models are sometimes evaluated as an independent assessor
- How does the model's performance compare to the performance of one assessor with respect to another?
 - One assessor produces the "ground truth" and the other produces the "predictions"

measures agreement: percent agreement

 Percent agreement: percentage of instances for which both assessors agree that the concept occurs or does not occur

5	

	yes	no
yes	Α	В
no	С	D

measures agreement: percent agreement

 Percent agreement: percentage of instances for which both assessors agree that the concept occurs or does not occur

	yes	no
yes	Α	В
no	С	D

$$\frac{(A+D)}{(A+B+C+D)}$$

measures agreement: percent agreement

 Percent agreement: percentage of instances for which both assessors agree that the concept occurs or does not occur

-			_
	yes	no	
yes	5	5	10
no	15	75	90
	20	80	•

% agreement = ???

measures agreement: percent agreement

 Percent agreement: percentage of instances for which both assessors agree that the concept occurs or does not occur

	yes	no	
yes	5	5	10
no	15	75	90
	20	80	•

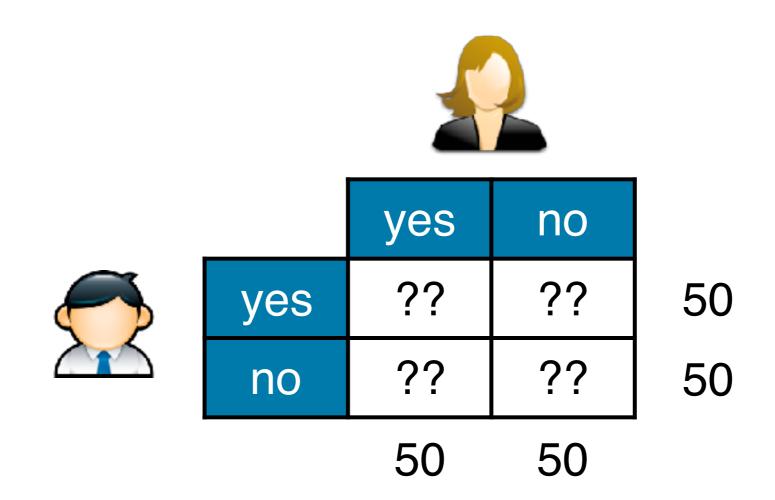

% agreement = (5 + 75) / 100 = 80%

measures agreement: percent agreement

- Problem: percent agreement does not account for agreement due to random chance.
- How can we compute the expected agreement due to random chance?
 - Option 1: assume unbiased assessors
 - Option 2: assume biased assessors

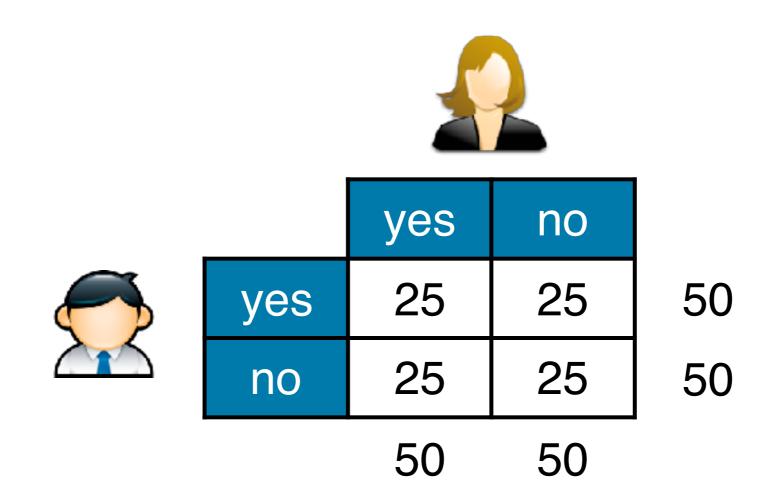

kappa agreement: chance-corrected % agreement

Option 1: unbiased assessors

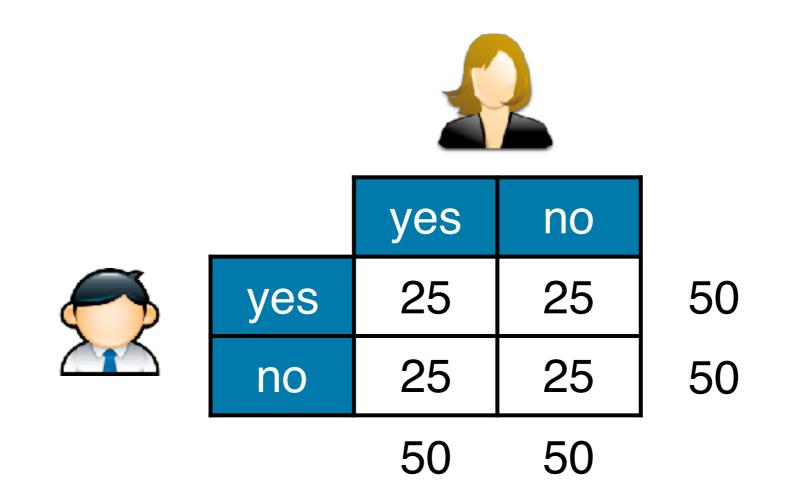

kappa agreement: chance-corrected % agreement

Option 1: unbiased assessors

kappa agreement: chance-corrected % agreement

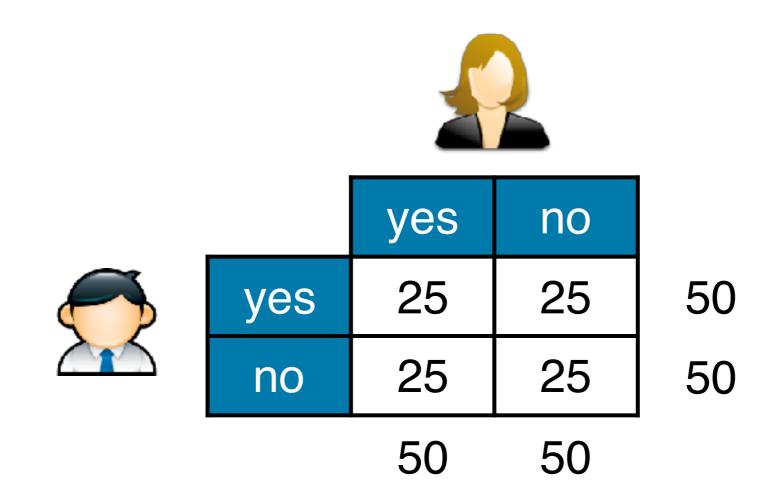

Option 1: unbiased assessors

random chance % agreement = ???

kappa agreement: chance-corrected % agreement

Option 1: unbiased assessors

random chance % agreement = (25 + 25)/100 = 50%

kappa agreement: chance-corrected % agreement

 Kappa agreement: percent agreement after correcting for the expected agreement due to random chance

$$\mathcal{K} = \frac{P(a) - P(e)}{1 - P(e)}$$

- P(a) = percent of observed agreement
- P(e) = percent of agreement due to random chance

kappa agreement: chance-corrected % agreement

 Kappa agreement: percent agreement after correcting for the expected agreement due to <u>unbiased</u> chance

	yes	no
yes	5	5
no	15	75
	20	80

	yes	no	
yes	25	25	50
no	25	25	50
	50	50	-

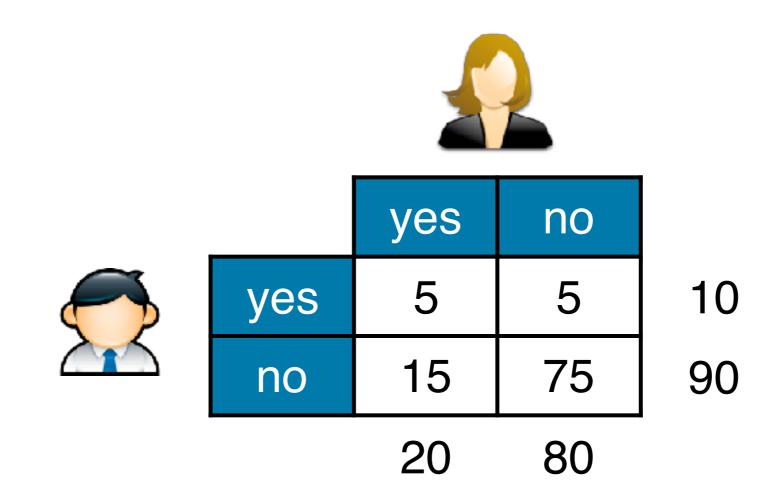

$$P(a) = \frac{5+75}{100} = 0.80$$

$$P(e) = \frac{25+25}{100} = 0.50$$

$$\mathcal{K} = \frac{P(a) - P(e)}{1 - P(e)} = \frac{0.80 - 0.50}{1 - 0.50} = 0.60$$

kappa agreement: chance-corrected % agreement

Option 2: biased assessors

biased chance % agreement = ???

kappa agreement: chance-corrected % agreement

 Kappa agreement: percent agreement after correcting for the expected agreement due to <u>biased</u> chance

80

 $P(a) = \frac{5+75}{100} = 0.80$ $P(e) = \left(\frac{10}{100} \times \frac{20}{100}\right) + \left(\frac{90}{100} \times \frac{80}{100}\right) = 0.74$

$$\mathcal{K} = \frac{P(a) - P(e)}{1 - P(e)} = \frac{0.80 - 0.74}{1 - 0.74} = 0.23$$

data annotation process

- INPUT: unlabeled data, annotators, coding manual
- OUTPUT: labeled data
 - using the latest coding manual, have <u>all</u> annotators label some previously unseen portion of the data (~10%)
 - 2. measure inter-annotator agreement (Kappa)
 - 3. **IF** agreement < X, **THEN**:
 - refine coding manual using disagreements to resolve inconsistencies and clarify definitions
 - return to 1

ELSE

have annotators label the remainder of the data

Predictive Analysis data annotation process

- What is good (Kappa) agreement?
- It depends on who you ask
- According to Landis and Koch, 1977:
 - 0.81 1.00: almost perfect
 - 0.61 0.70: substantial
 - 0.41 0.60: moderate
 - 0.21 0.40: fair
 - 0.00 0.20: slight
 - < 0.00: no agreement</p>

Predictive Analysis data annotation process

- Question: requests information about the course content
- Answer: contributes information in response to a question
- Issue: expresses a problem with the course management
- Issue Resolution: attempts to resolve a previously raised issue
- Positive Ack: positive sentiment about a previous post
- Negative Ack: negative sentiment about a previous post
- Other: serves a different purpose

data annotation process

	MTurk Workers	MV and Expert	
	$\kappa_{ m f}$	$\kappa_{ m c}$	
Question	0.569	0.893	
Answer	0.414	0.790	
Issue	0.421	0.669	
Issue Resolution	0.286	0.635	
Positive Ack.	0.423	0.768	
Negative Ack.	0.232	0.633	
Other	0.337	0.625	

Predictive Analysis questions

- Is a particular concept appropriate for predictive analysis?
- What should the unit of analysis be?
- What is a good feature representation for this task?
- How should I divide the data into training and test sets?
- What type of learning algorithm should I use?
- How should I evaluate my model's performance?

turning data into (training and test) instances

- For many text-mining applications, turning the data into instances for training and testing is fairly straightforward
- Easy case: instances are self-contained, independent units of analysis
 - topic categorization: instances = documents
 - opinion mining: instances = product reviews
 - bias detection: instances = political blog posts
 - emotion detection: instances = support group posts

Topic Categorization

predicting health-related documents

features

w_1	w_2	w_3		w_n	label
1	1	0		0	health
0	0	0		0	other
0	0	0		0	other
0	1	0	•••	1	other
:	•	•		0	•
1	0	0	•••	1	health

Opinion Mining

predicting positive/negative movie reviews

features

w_1	w_2	w_3	:	w_n	label
1	1	0	•••	0	positive
0	0	0		0	negative
0	0	0		0	negative
0	1	0		1	negative
:	• • • •	•		0	:
1	0	0	•••	1	positive

Bias Detection

predicting liberal/conservative blog posts

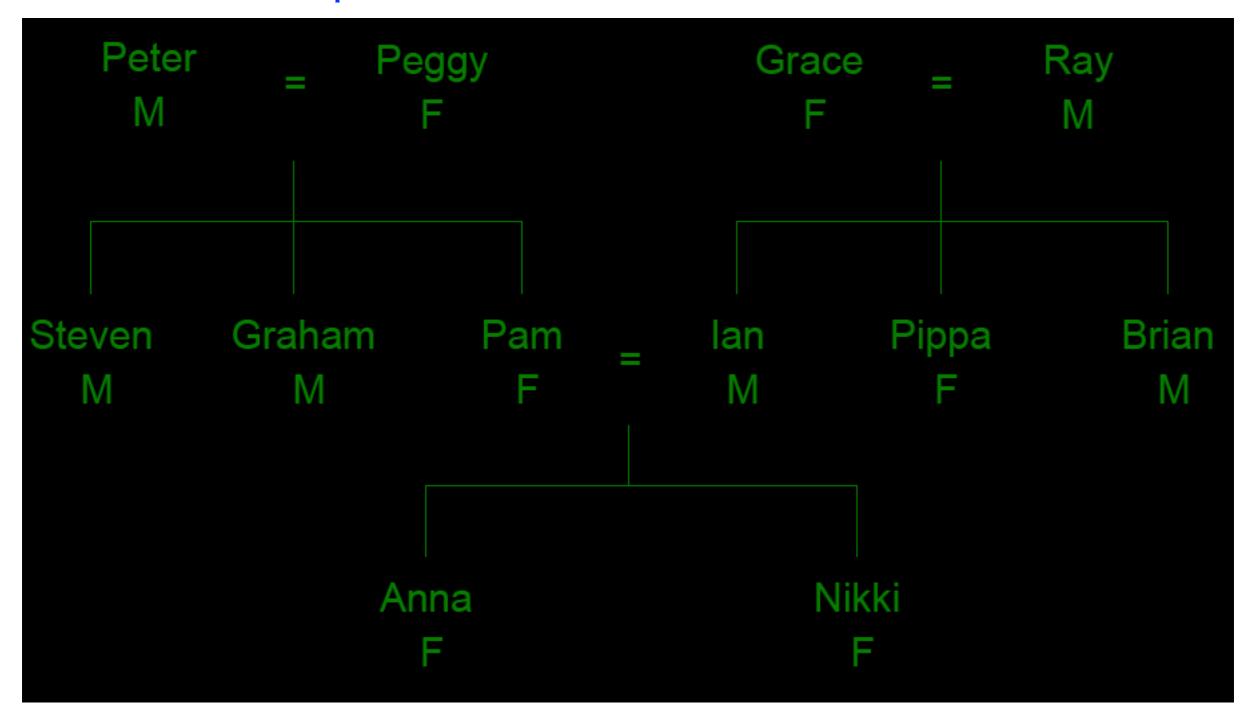

features

w_1	w_2	w_3		w_n	label
1	1	0	•••	0	liberal
0	0	0		0	conservative
0	0	0		0	conservative
0	1	0		1	conservative
:	•	• • •		0	• • •
1	0	0	•••	1	liberal

turning data into (training and test) instances

- A not-so-easy case: relational data
- The concept to be learned is a <u>relation</u> between pairs of objects

example of relational data: Brother(X,Y)

(example borrowed and modified from Witten et al. textbook)

instances

Predictive Analysis

example of relational data: Brother(X,Y)

features

concept

name_1	gender_1	mother_1	father_1	name_2	gender_2	mother_2	father_2	brother
steven	male	peggy	peter	graham	male	peggy	peter	yes
lan	male	grace	ray	brian	male	grace	ray	yes
anna	female	pam	ian	nikki	female	pam	ian	no
pippa	female	grace	ray	brian	male	grace	ray	no
steven	male	peggy	peter	brian	male	grace	ray	no
anna	female	pam	ian	brian	male	grace	ray	no

- A not-so-easy case: relational data
- Each instance should correspond to an object <u>pair</u> (which may or may not share the relation of interest)
- May require features that characterize properties of the pair

instances

Predictive Analysis

example of relational data: Brother(X,Y)

features

concept

name_1	gender_1	mother_1	father_1	name_2	gender_2	mother_2	father_2	brother
steven	male	peggy	peter	graham	male	peggy	peter	yes
lan	male	grace	ray	brian	male	grace	ray	yes
anna	female	pam	ian	nikki	female	pam	ian	no
pippa	female	grace	ray	brian	male	grace	ray	no
steven	male	peggy	peter	brian	male	grace	ray	no
anna	female	pam	ian	brian	male	grace	ray	no

(can we think of a better feature representation?)

instances

Predictive Analysis

example of relational data: Brother(X,Y)

features

concept

gender_1	gender_2	same parents	brother
male	male	yes	yes
male	male	yes	yes
female	female	no	no
female	male	yes	no
male	male	no	no
	•	••••	:
female	male	no	no

- A not-so-easy case: relational data
- There is still an issue that we're not capturing! Any ideas?
- Hint: In this case, should the predicted labels really be independent?

turning data into (training and test) instances

Brother(A,B) = yes

Brother(B,C) = yes

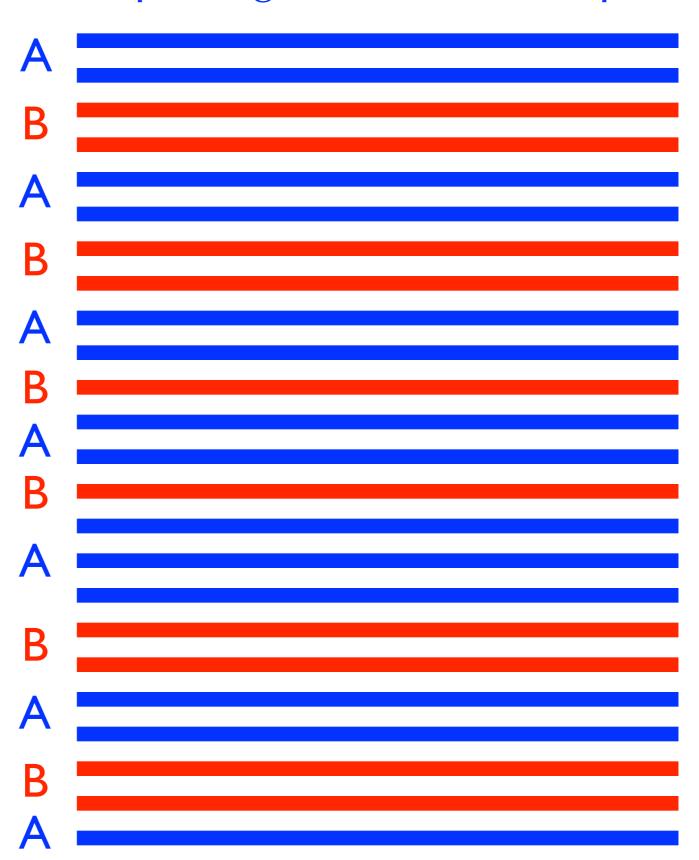

Brother(A,C) = no

- In this case, what we would really want is:
 - a method that does joint prediction on the test set
 - a method whose joint predictions satisfy a set of known properties about the data as a whole (e.g., transitivity)

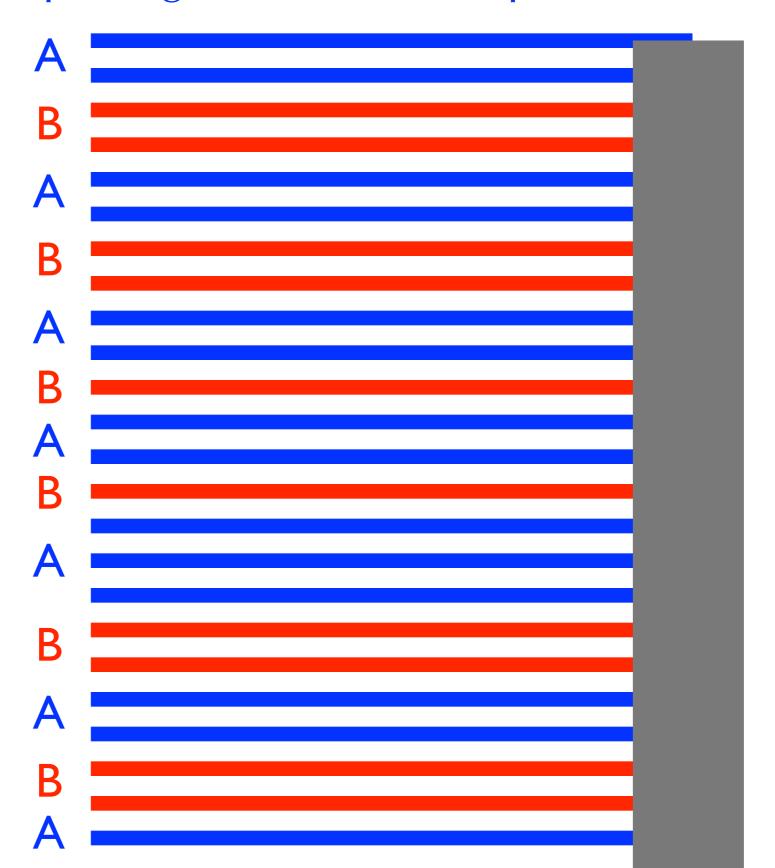

- There are learning algorithms that incorporate relational constraints between predictions
- However, they are beyond the scope of this class
- We'll be covering algorithms that make independent predictions on instances
- That said, many algorithms output prediction confidence values
- Heuristics can be used to disfavor inconsistencies

- Examples of relational data in text-mining:
 - information extraction: predicting that a word-sequence belongs to a particular class (e.g., person, location)
 - topic segmentation: segmenting discourse into topically coherent chunks

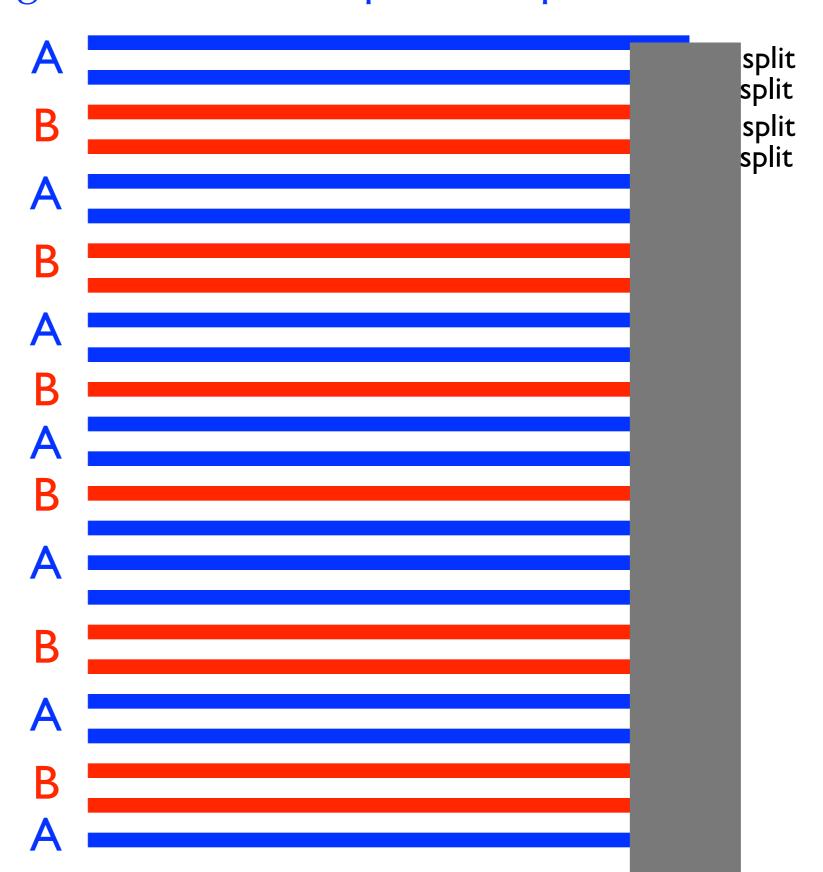

topic segmentation example

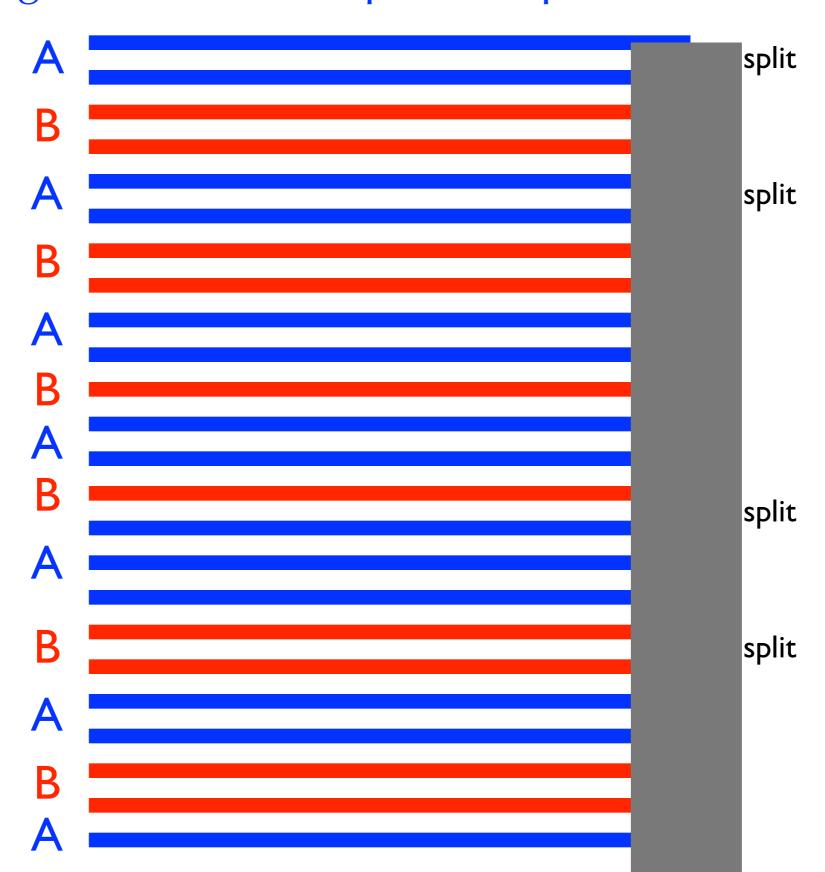

topic segmentation example: instances

topic segmentation example: independent instances?

topic segmentation example: independent instances?

Predictive Analysis questions

- Is a particular concept appropriate for predictive analysis?
- What should the unit of analysis be?
- How should I divide the data into training and test sets?
- What is a good feature representation for this task?
- What type of learning algorithm should I use?
- How should I evaluate my model's performance?

- We want our model to "learn" to recognize a concept
- So, what does it mean to <u>learn</u>?

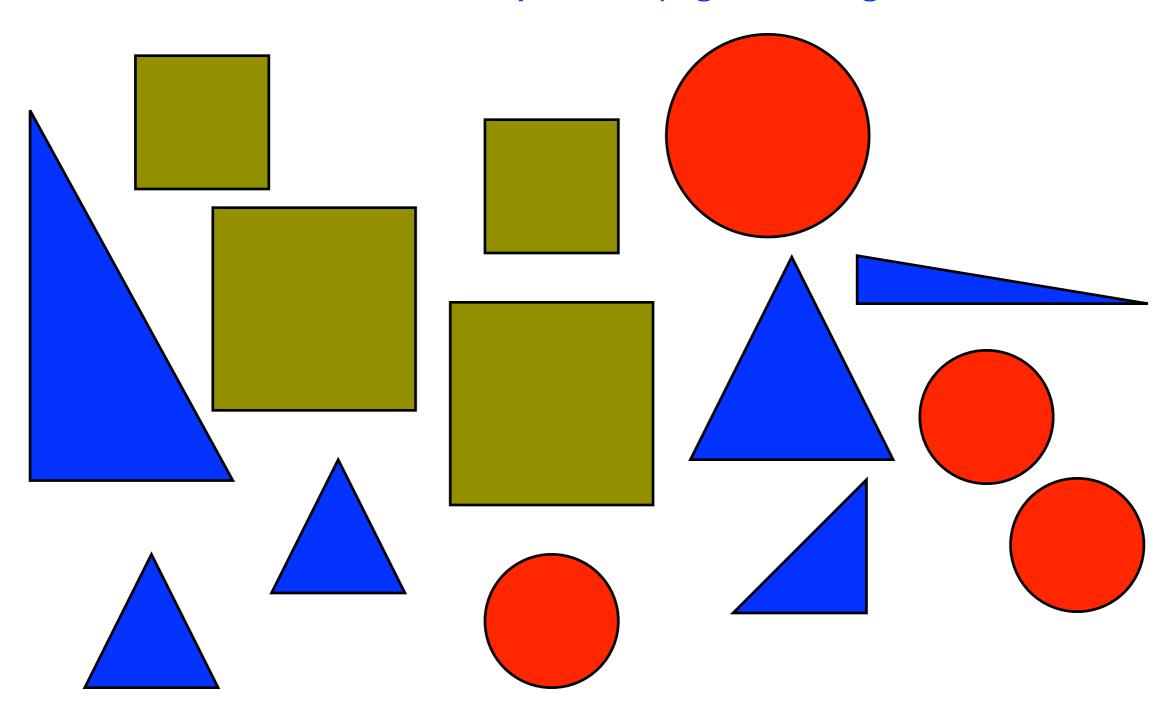

The machine learning definition of *learning*:

A machine *learns* with respect to a particular task T, performance metric P, and experience E, if the system improves its <u>performance P</u> at task T following experience E. -- Tom Mitchell

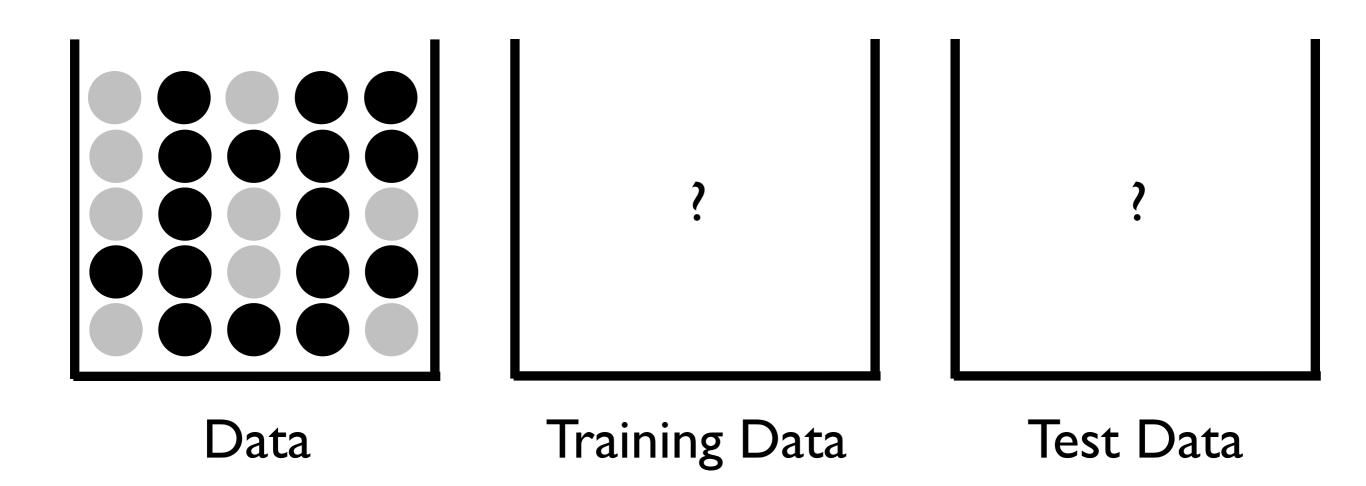

- We want our model to improve its generalization performance!
- That is, its performance on previously unseen data!
- Generalize: to derive or induce a general conception or principle from particulars. -- Merriam-Webster
- In order to test generalization performance, the training and test data cannot be the same.
- Why?

Training data + Representation

what could possibly go wrong?

- While we don't want to test on training data, models usually perform the best when the training and test set are derived from the same "probability distribution".
- What does that mean?

positive instances negative instances

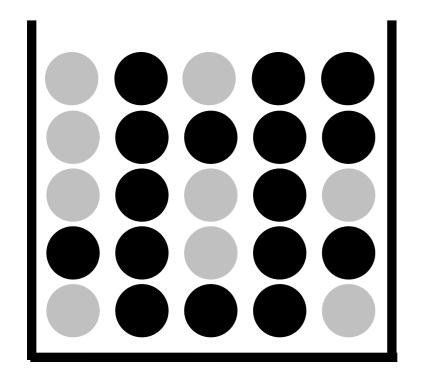

training and test data

• Is this a good partitioning? Why or why not?

positive instances

negative instances

Random Sample

Random Sample

Data

Training Data

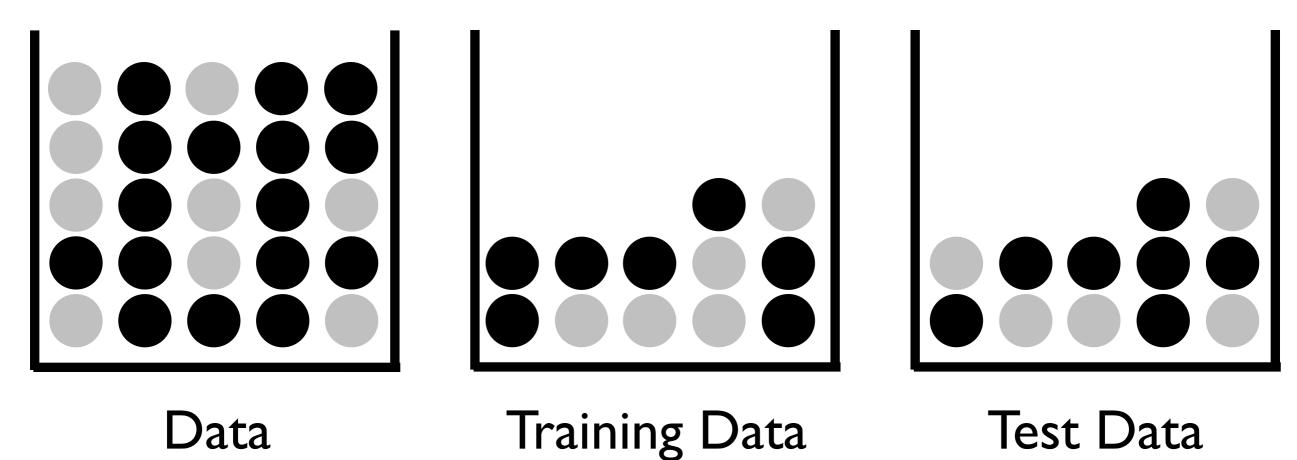

Test Data

positive instances

negative instances

training and test data

 On average, random sampling should produce comparable data for training and testing

positive instances

negative instances

- Models usually perform the best when the training and test set have:
 - a similar proportion of positive and negative examples
 - a similar co-occurrence of feature-values and each target class value

- Caution: in some situations, partitioning the data randomly might inflate performance in an unrealistic way!
- How the data is split into training and test sets determines what we can claim about generalization performance
- The appropriate split between training and test sets is usually determined on a case-by-case basis

Predictive Analysis discussion

- Spam detection: should the training and test sets contain email messages from the <u>same sender</u>, <u>same recipient</u>, and/or <u>same timeframe</u>?
- Topic segmentation: should the training and test sets contain potential boundaries from the <u>same discourse</u>?
- Opinion mining for movie reviews: should the training and test sets contain reviews for the <u>same movie</u>?
- Sentiment analysis: should the training and test sets contain blog posts from the <u>same discussion thread</u>?

Predictive Analysis questions

- Is a particular concept appropriate for predictive analysis?
- What should the unit of analysis be?
- How should I divide the data into training and test sets?
- What type of learning algorithm should I use?
- What is a good feature representation for this task?
- How should I evaluate my model's performance?

Predictive Analysis three types of classifiers

- Linear classifiers
- Decision tree classifiers
- Instance-based classifiers

Predictive Analysis three types of classifiers

- All types of classifiers learn to make predictions based on the input feature values
- However, different types of classifiers combine the input feature values in different ways
- Chapter 3 in the book refers to a trained model as knowledge representation

linear classifiers: perceptron algorithm

$$y = \begin{cases} 1 & \text{if } w_0 + \sum_{j=1}^n w_j x_j > 0 \\ 0 & \text{otherwise} \end{cases}$$

linear classifiers: perceptron algorithm

$$y = \begin{cases} 1 & \text{if } w_0 + \sum_{j=1}^n w_j x_j > 0 \\ 0 & \text{otherwise} \end{cases}$$

parameters learned by the model predicted value (e.g., I = positive, 0 = negative)

linear classifiers: perceptron algorithm

test instance

f_1	f_2	f_3
0.5	1	0.2

model weights

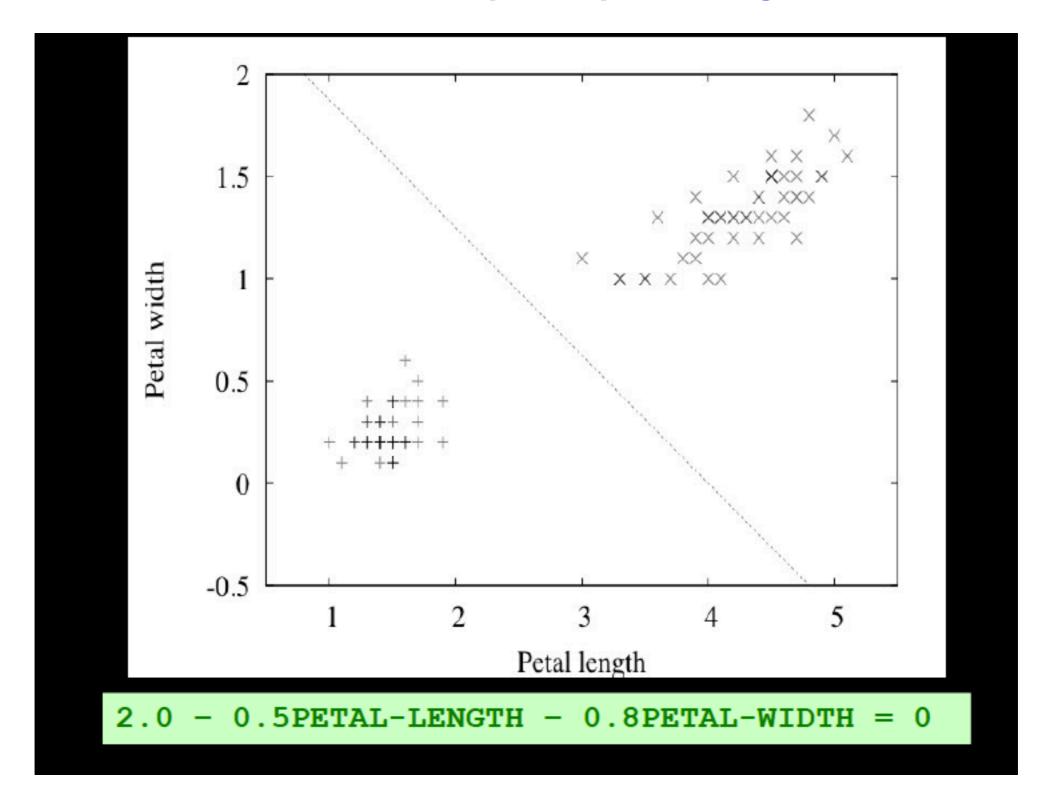

w_0	w_1	w_2	w_3
2	-5	2	1

output =
$$2.0 + (0.50 \times -5.0) + (1.0 \times 2.0) + (0.2 \times 1.0)$$

$$output = 1.7$$

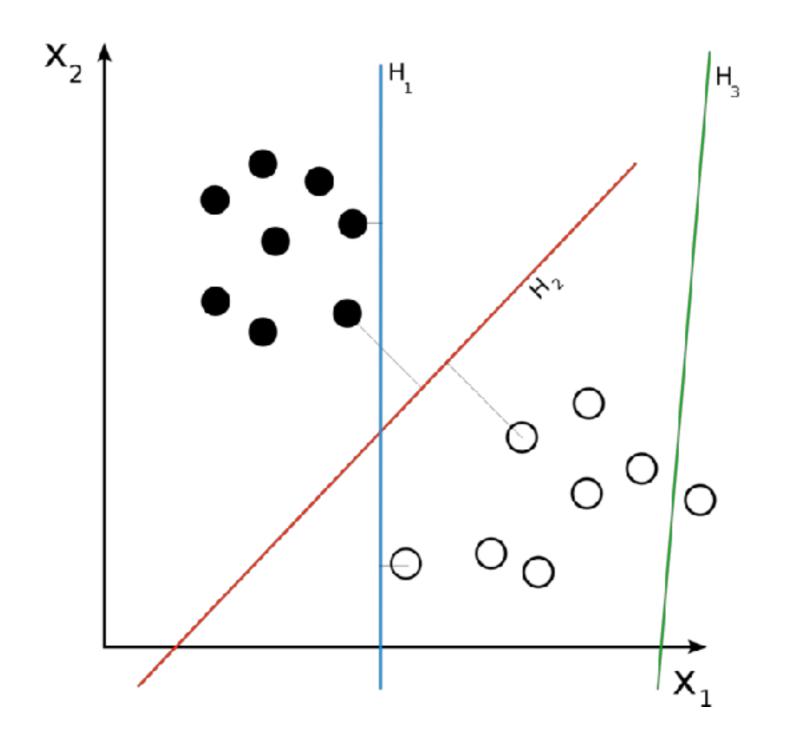

output prediction = positive

linear classifiers: perceptron algorithm

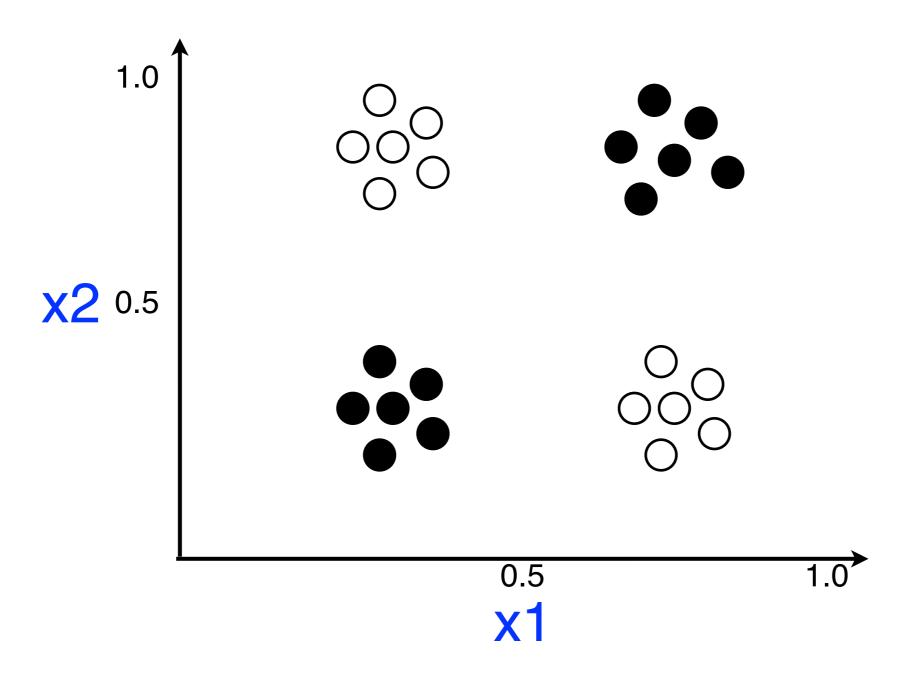

(two-feature example borrowed from Witten et al. textbook)

linear classifiers: perceptron algorithm

linear classifiers: perceptron algorithm

 Would a linear classifier do well on positive (black) and negative (white) data that looks like this?

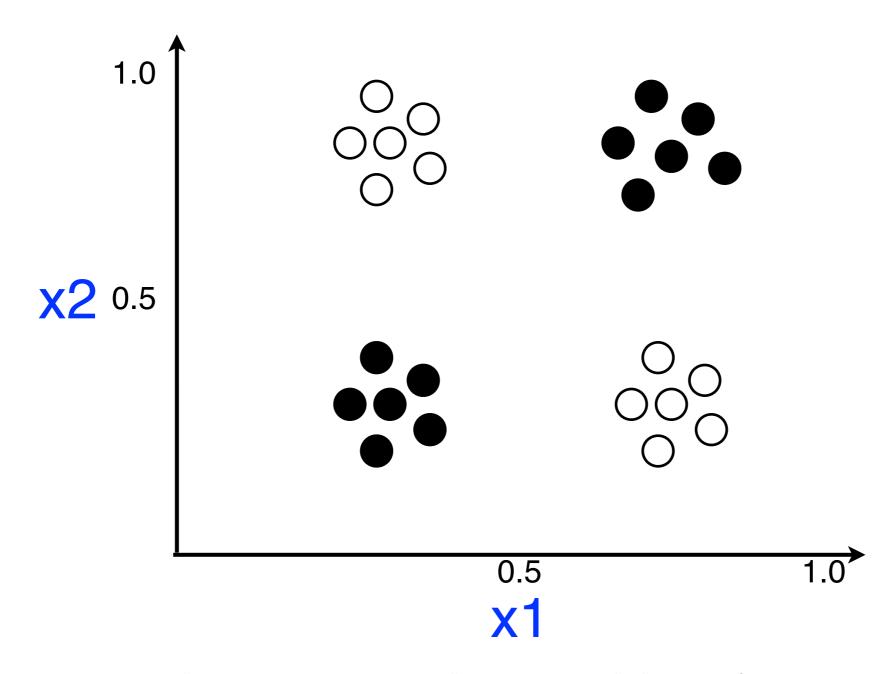

Predictive Analysis three types of classifiers

- Linear classifiers
- Decision tree classifiers
- Instance-based classifiers

example of decision tree classifier: Brother(X,Y)

decision tree classifiers

 Draw a decision tree that would perform perfectly on this training data!

Predictive Analysis three types of classifiers

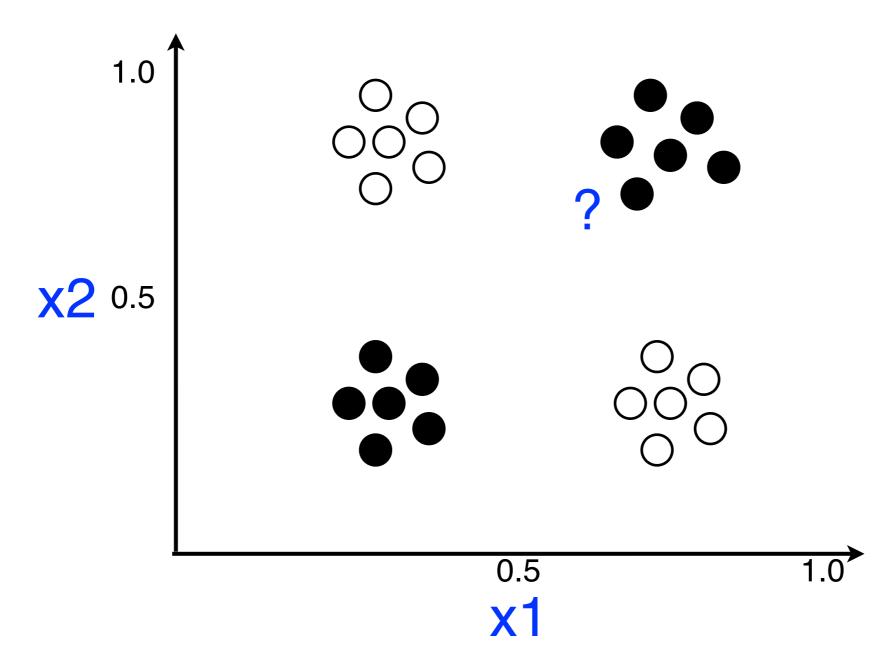

- Linear classifiers
- Decision tree classifiers
- Instance-based classifiers

instance-based classifiers

 predict the class associated with the most similar training examples

instance-based classifiers

 predict the class associated with the most similar training examples

Predictive Analysis instance-based classifiers

- Assumption: instances with similar feature values should have a similar label
- Given a test instance, predict the label associated with its nearest neighbors
- There are many different similarity metrics for computing distance between training/test instances
- There are many ways of combining labels from multiple training instances

Predictive Analysis questions

- Is a particular concept appropriate for predictive analysis?
- What should the unit of analysis be?
- How should I divide the data into training and test sets?
- What is a good feature representation for this task?
- What type of learning algorithm should I use?
- How should I evaluate my model's performance?
